CALCULATING THERMODYNAMIC PROPERTIE

Thermo-Calc Software

CALCULATING THERMODYNAMIC PROPERTIES

TC-PRISMA – A Tool for Simulation of Precipitation Reactions in Alloys

Henrik Strandlund, Xiaogang Lu, Qing Chen Presented by Paul Mason

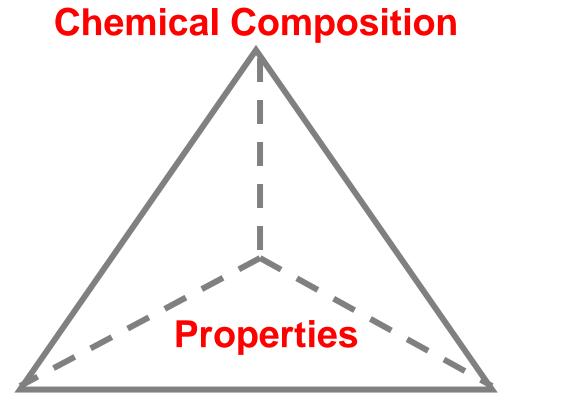

Outline

- Background
- Simulations of precipitation
- Models
- New software tool: TC-PRISMA

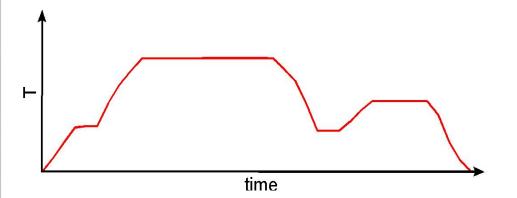

Microstructure

Processing

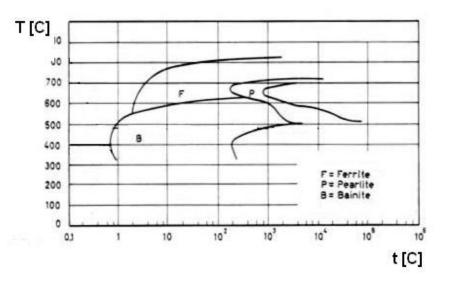

Background

Industrial Heat treatment

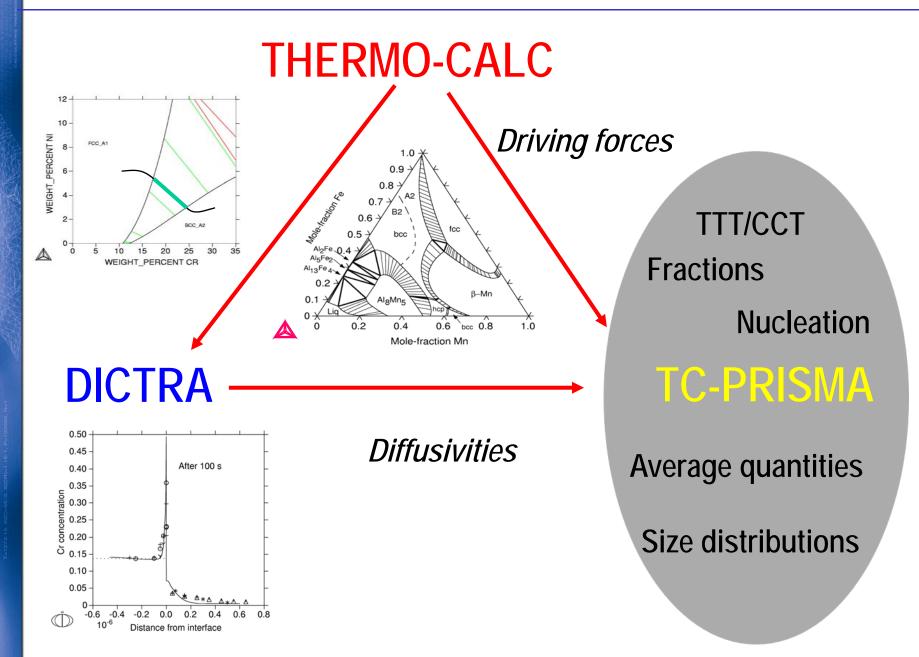

- Optimize processes
- Control the microstructure
- Tailor material properties

Background

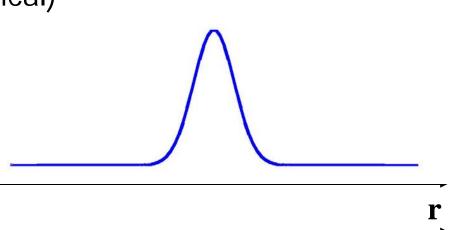

Models: KWN

- Kampmann Wagner (Numerical)
- Nucleation, Growth and Coarsening

- Different size classes
- Temporal evolution of particle size distributions

Ν

$$\frac{\partial N_k}{\partial t} = -\frac{\partial (N_k v_k)}{\partial r} + j_k$$

Nucleation

Classical Nucleation Theory

$$j = Z\beta N e^{-\frac{\Delta G}{kT}} e^{-\frac{\tau}{t}}$$

- Z Zeldovich factor
- N number of nucleation sites
- τ Incubation time

- β atomic attachment rate
- ΔG critical driving force for nucleation

Multicomponent effects (e.g. difference in diffusivities) are taken into account in $\boldsymbol{\beta}$

Do not consider diffusion inside precipitate (unlike DICTRA)

• Want a model capable of treating different growth modes such as **diffusion-controlled**, **interface-controlled**, or **mixed mode growth** without detailed solution of composition profile in multi-component matrix phase

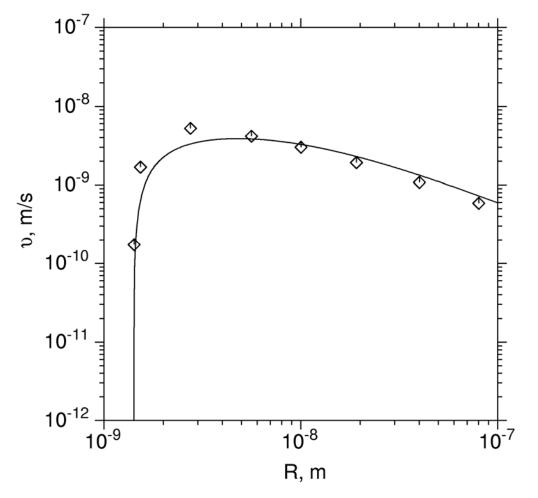

•Large supersaturation, para-equilibrium, and NPLE can be taken into account

$$v(c_i^P - c_i^I) = c_i^I M_i (\mu_i^M - \mu_i^I) / \xi_i R$$
$$\mu_i^P = \mu_i^I$$

Q. Chen, J. Jeppsson, J. Ågren, Acta Mater. 2008;56:1890

Models: Growth rate (new model)

Fe-2%Cr-0.05%C, M23C6 from ferrite, local equilibrium, Cr-diffusion controlled

Q. Chen, J. Jeppsson, J. Ågren, Acta Mater. 2008;56:1890

Calculates:

- TTT/CCT diagrams
- Temporal evolution of particles distributions
- Average particle radius as a function of time
- Phase fractions
- Average composition in precipitates and matrix
- Interfacial compositions for each particle size
- Nucleation rate
- Growth rate for each particle size
- Critical radius as a function of time
- User defined functions

Precipitation of cementite

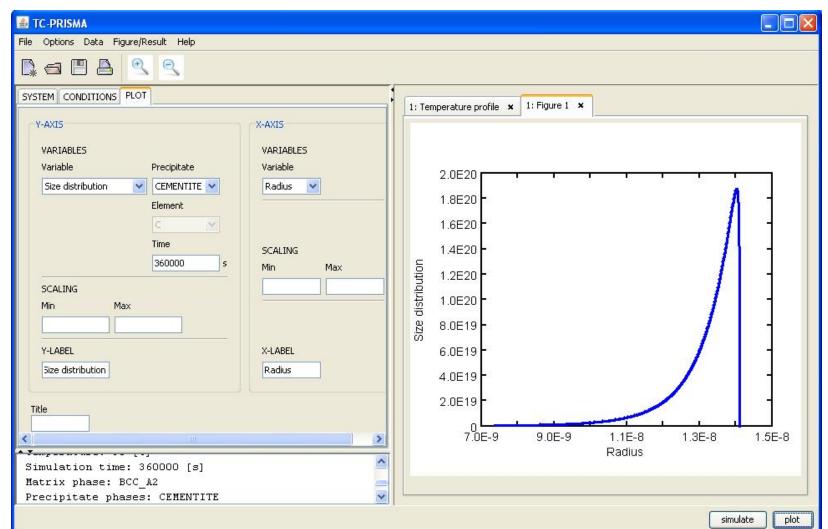

Calculation of volume fraction of cementite for low alloyed steel at 311K compared to experimental data

Precipitation of cementite

Calculation of size distribution of cementite particles for low alloyed steel at 311K after 100 hours

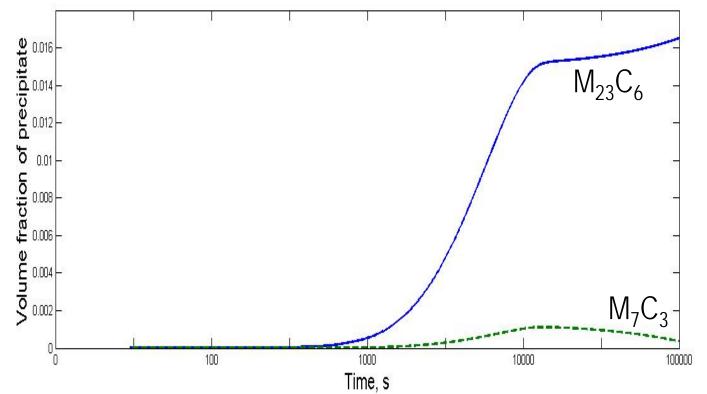

Precipitation of $M_{23}C_6$ and M_7C_3

Precipitation of M₂₃C₆ from ferrite in Fe-12%Cr-0.1%C at 1053K

 \sim Metastable M₇C₃ forms at the beginning and desolves

Similar calc by Inden and Schneider using DICTRA took days/hrs. This calc in TC-PRISMA on a timescale of minutes (and includes larger no. of particles.

Precipitation of M₂₃C₆ from austenite

Precipitation of M₂₃C₆ from austenite at 923 K in steel AISI316. Composition (wt%): Fe-0.05C-16Cr-1.5Mn-2.3Mo-11Ni-0.6Si. Benchmark calc: Takes approx. 30 minutes

Summary

- A new software tool for simulation of precipitation reactions in multicomponent, multiphase alloys, TC-PRISMA, is being developed by Thermo-Calc Software
- The KWN approach is taken, but a completely new model for the growth rate is applied
- Classical nucleation theory, but multicomponent effects are taken into account
- A new database containing interfacial energies for steels is under development
